# Communication Systems and Protocols

## Session 11: Networks

# Clicker Session: Recapitulation

■ <https://arsnova.eu/mobile/#id/33969518>

# Recapitulation

- Automotive busses
  - FlexRay

# Networks

# Definition: Network

An arrangement of intersecting horizontal and vertical lines:  
*a spider constructs a complex network of several different kinds of threads*

A number of interconnected computers, machines, or operations:  
*a computer network*

1. Computers: A group of interconnected (via cable and/or wireless) computers and peripherals that is capable of sharing software and hardware resources between many users. The Internet is a global network of networks. See also local area network and wide area network.
2. Communications: A system that enables users of telephones or data communications lines to exchange information over long distances by connecting with each other through a system of routers, servers, switches, and the like.

Sources: Oxford Dictionaries

# Network vs. Bus

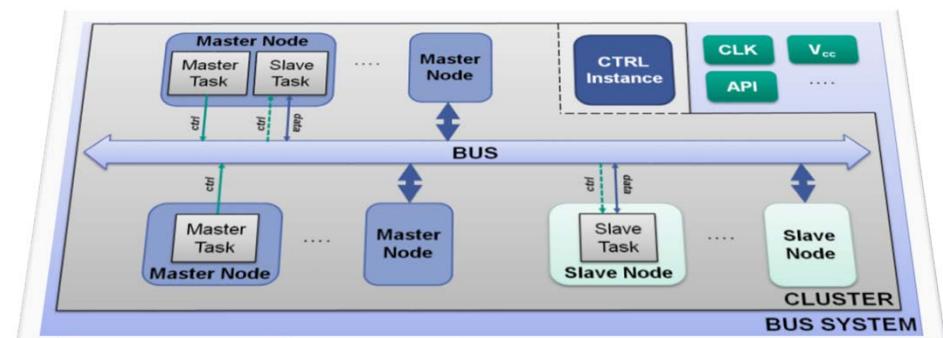

## ■ Networks:

- different and multiple communication channels are possible
- Error resistance can be higher due to alternative routing
- variable Bandwidth due to multiple, parallel channels

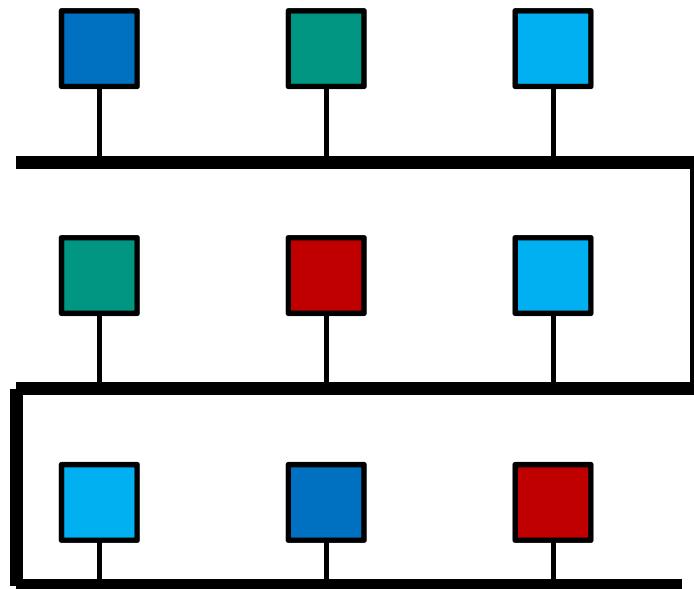

## ■ Bus:

- dedicated and fixed physical communication channel
- bandwidth is limited by bus line
- Communication bandwidth is constant for growing number of nodes → bad scalability

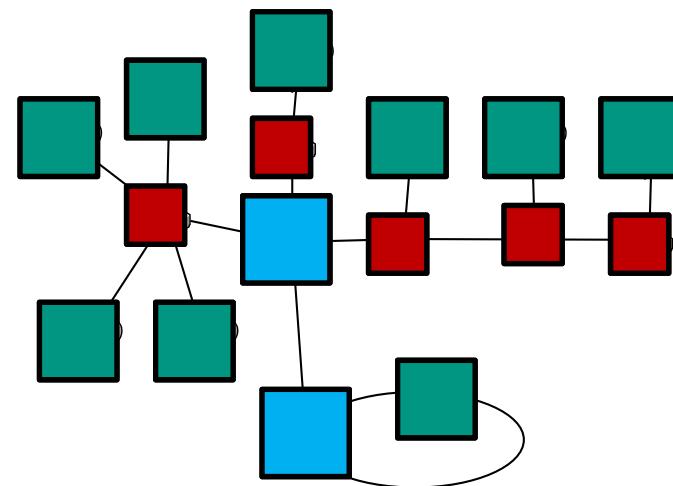

# Benefits of Network

## System Setup using a bus

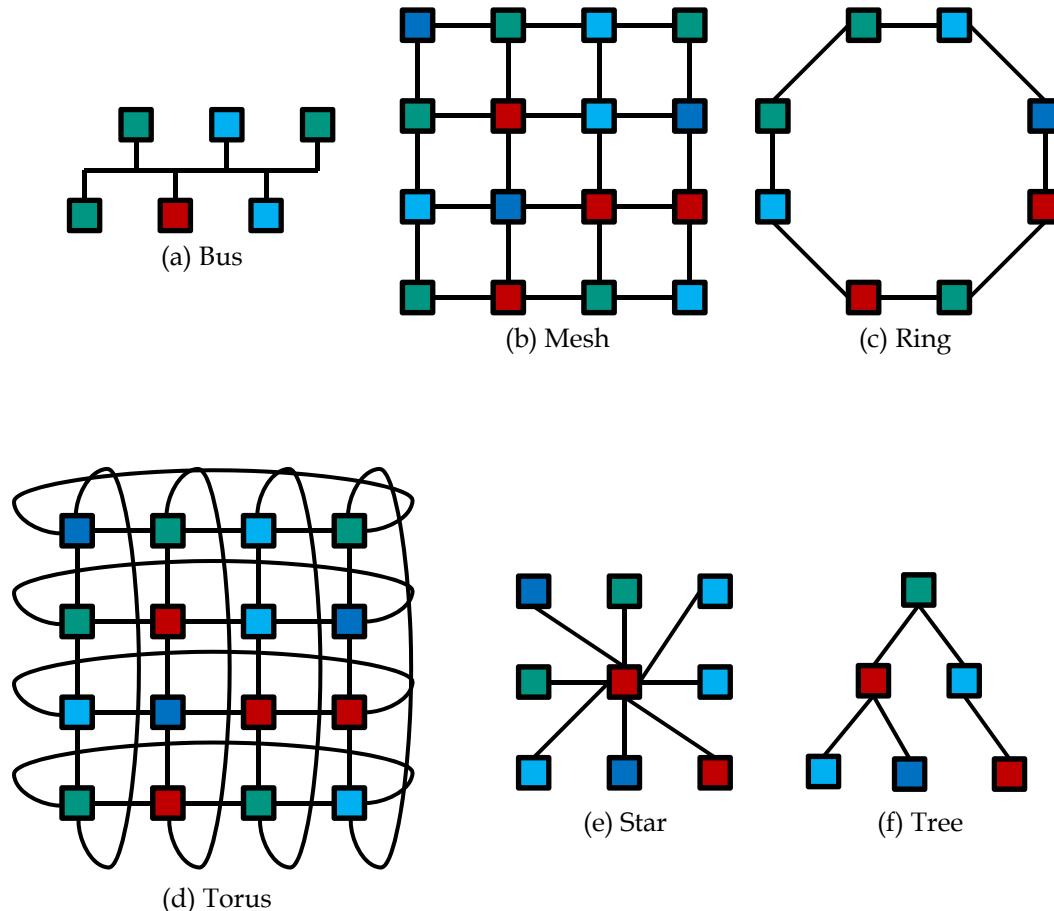

## System Setup using a Network

- Less and shorter communication lines
- Multiple connections at the same time possible
- Very flexible
- Efficient use of bandwidth

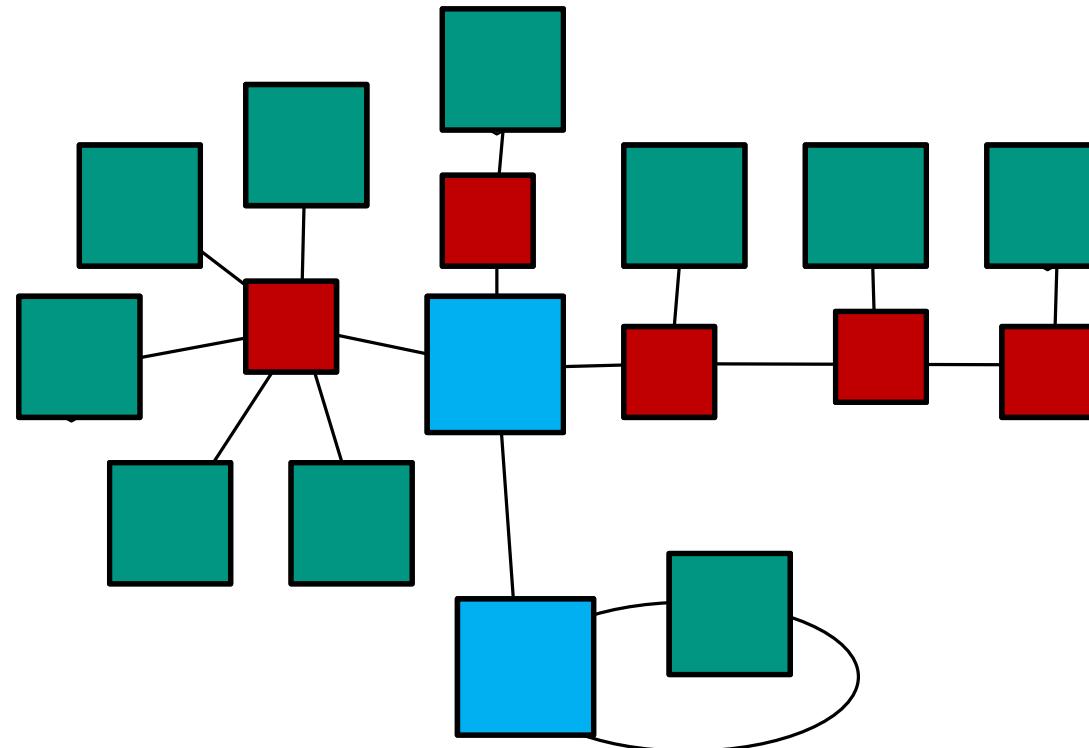

# Networks – physical Structure

- Different components interconnected
  - Computing Nodes
  - Routers
  - Switches
  - ...
- Differentiation between geometric / logic
- Geometric topologies can be ring, line, star, and any combinations

# Example of a physical Structure

- Local Area Network

# Definitions

## **Node**

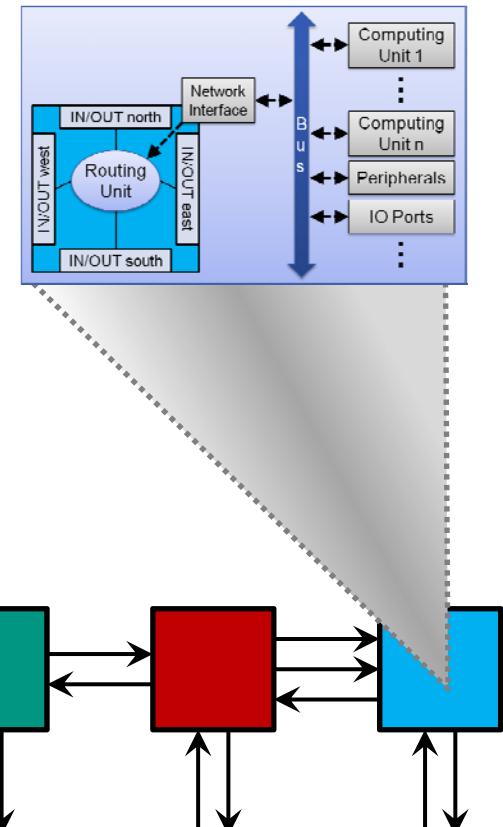

- Basic communication entity that gets connected in a network
- A network node (normally) contains Ports, Routing Unit, Network Interface and a Tile

## **Tile**

- A Tile is the units that produces and consumes the data that is to be transported over a network
- Computing Units, Peripherals, Memory, Input/Output ports, etc.

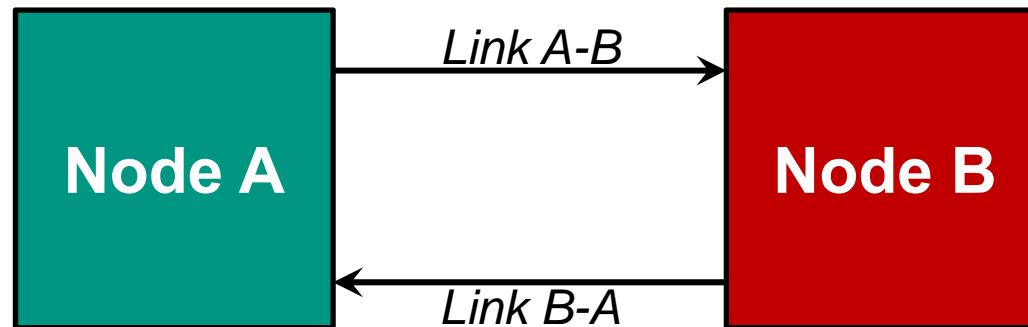

## **Link**

- Communication path between neighboring nodes
- unidirectional
- multiple links between two tile can exist (in either direction)

# Network Link

- Physical communication channel between neighboring nodes
- Unidirectional
- Link has fixed data width
- Multiple links between two nodes can exist (in either direction)
  - concurrent transmissions
  - or
  - aggregation to achieve higher throughput/bandwidth

# Definitions II

## ***Hop***

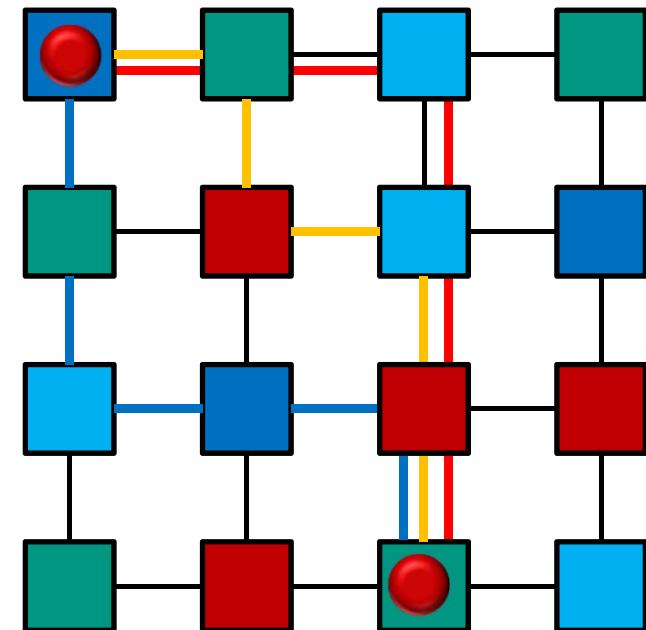

- The transmission of data from one node to the neighboring node

## ***Diameter***

- The Diameter of a network is the maximum number of hops between any pair of nodes in a network

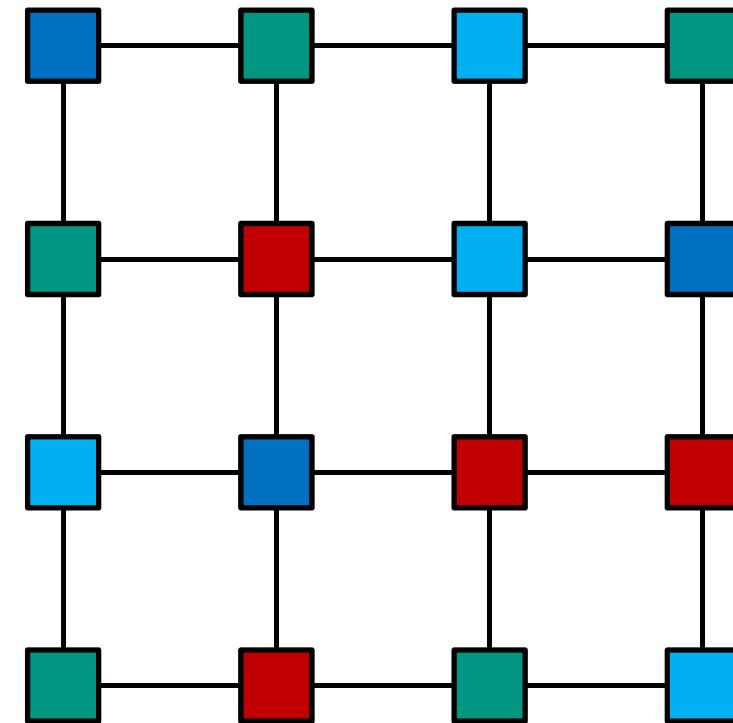

## ***Manhattan Distance***

- Layout of the network must be a mesh based grid
- physical distance following the edges
- all paths that always move towards the target have same distance

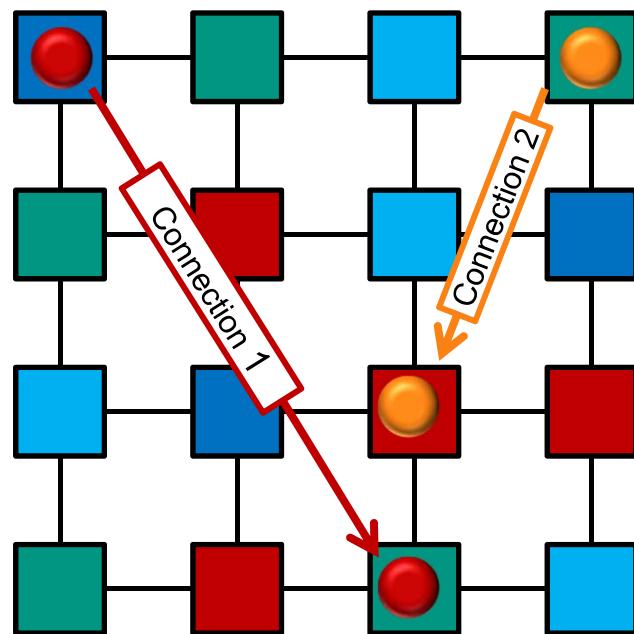

# Communication Setup in Networks

- Need for logic connections between nodes (channels)
- Different paths can be conceived to connect nodes.
- Routing
  - find a suitable communication path

# Connection Types

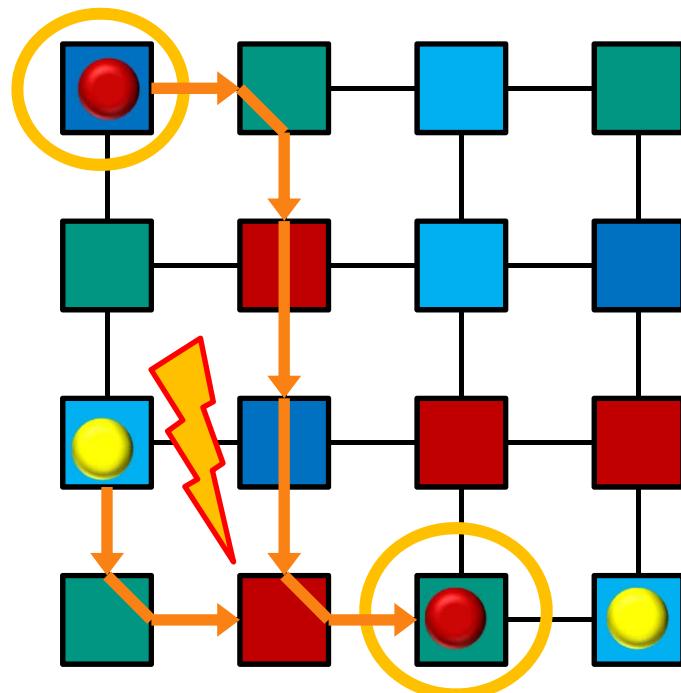

- Establish logical communication channel between nodes
- Multiple concurrent connections can exist

- **Two general types of connection**
  - Circuit Switching
  - Packet Switching

# Circuit Switching

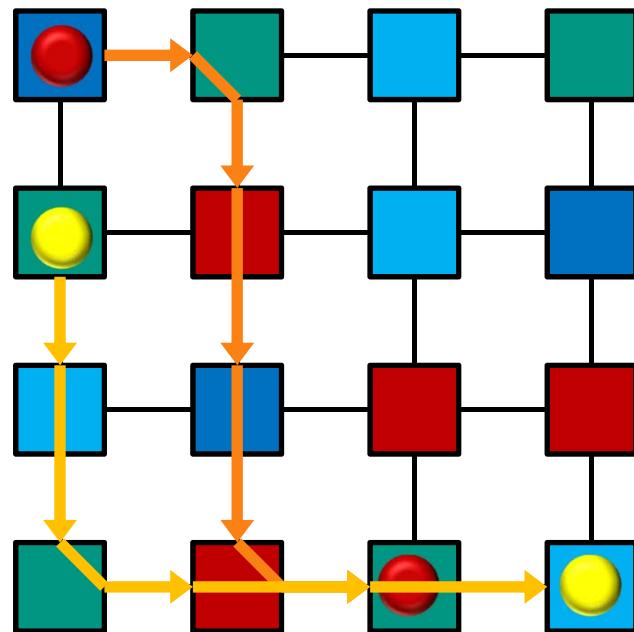

- Nodes communicate over a fixed path
  - Path is established for the full communication cycle
  - Path is used exclusively, can not be used for a second communication

- Pros & Cons
    - No interference (on logic level)
    - Other communication paths may be blocked off
    - Guaranteed throughput possible
  - Example: Analog telephone network

# Packet Switching

- Data is send in consecutive packets
- Path is established for the duration needed to send one packet
- Path can be used in a time multiplexed fashion by multiple communication processes

## ■ Pros & Cons

- Different routes of packets can lead to different arrival sequence
- Ordering of packets may be necessary (packet ID)
- Guarantees for network behavior difficult to give
- Less blocking of communication paths

# Comparison

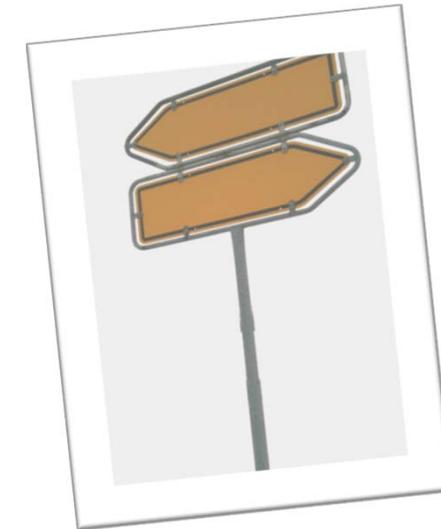

Circuit Switching		Packet Switching	
Pros	Cons	Pros	Cons
<ul style="list-style-type: none"> <li>• good for streaming data</li> <li>• guaranteed throughput</li> <li>• fast</li> <li>• simple routers</li> <li>• high throughput</li> <li>• real-time capable</li> </ul>	<ul style="list-style-type: none"> <li>• can block other communication</li> <li>• inefficient use of communication resources (for sporadic communication)</li> <li>• Setup required prior to communication start</li> </ul>	<ul style="list-style-type: none"> <li>• good for sporadic data transfers</li> <li>• flexible</li> <li>• multiplexing of paths possible</li> <li>• efficient usage of communication resources (links)</li> <li>• Failure tollerant (multiple paths to target node)</li> </ul>	<ul style="list-style-type: none"> <li>• complex routers</li> <li>• additional control overhead</li> <li>• additional local storage needed</li> <li>• varying latencies possible</li> <li>• behavior hard to predict</li> </ul>

# Routing

# The idea behind Routing

- Routing Problem
  - Connect data source with data sink
  - Decision on what paths to use
  - has to be integrated into the communication system (i.e. one or more network nodes, router,...)
  
- Possible Goals for Routing Algorithm:
  - Find short routes
  - Reduce routing overhead
  - Adaptability to...
    - changes in topology (node or link failures)
    - varying traffic loads
  - Avoid routing loops
  - ...

# Definitions

## **Loop**

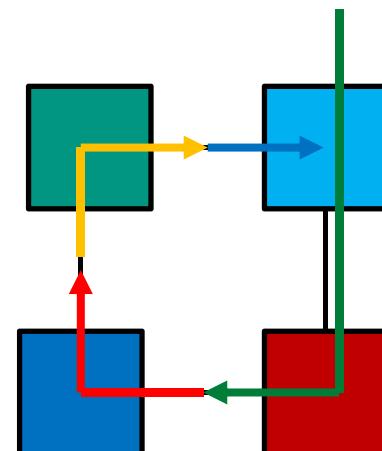

- A Loop is a path in a network that leads back to its starting point

## **Deadlock**

- A situation where a link is blocked by one transmission that is waiting for the other transmission to finish is called a deadlock.
- No communication is possible in case of a deadlock

## **Livelock**

- Data is forwarded through a network without reaching its destination
- Counterpart to deadlock

# Routing Mechanism

- Each node needs to know what to do with a data packet
  - Pass it on or not?
  - Which outgoing link is to be used?
- Knowledge is gained from the routing algorithm
  - Source routing  $\leftarrow \rightarrow$  distributed routing
  - Static routing  $\leftrightarrow$  Adaptive routing

# Pathfinding / Routing

## Static Routing

- predefined during design time
  - generates fixed routing information for nodes
- 
- + simple nodes
  - + fast pathfinding due to precomputation
  - not flexible
  - susceptible to defective nodes
  - no runtime adaptation

## Adaptive Routing

- routing information is computed during runtime of the system
  - the best path to a desired destination can change during operation
  - knowledge of network status is necessary
- 
- + highly flexible
  - + scalable
  - computationally expensive
  - route finding slow due to internal computation

# Pathfinding / Routing

## Source Routing

- Sending node is defining the complete route for packet
  - Information is part of the header of the packet
- 
- + Optimal routings possible
  - + Low complexity for intermediate routers
  - Protocol overhead, complete routing information is transported to the network
  - Overhead depends on path taken through the network

## Distributed (cooperative) Routing

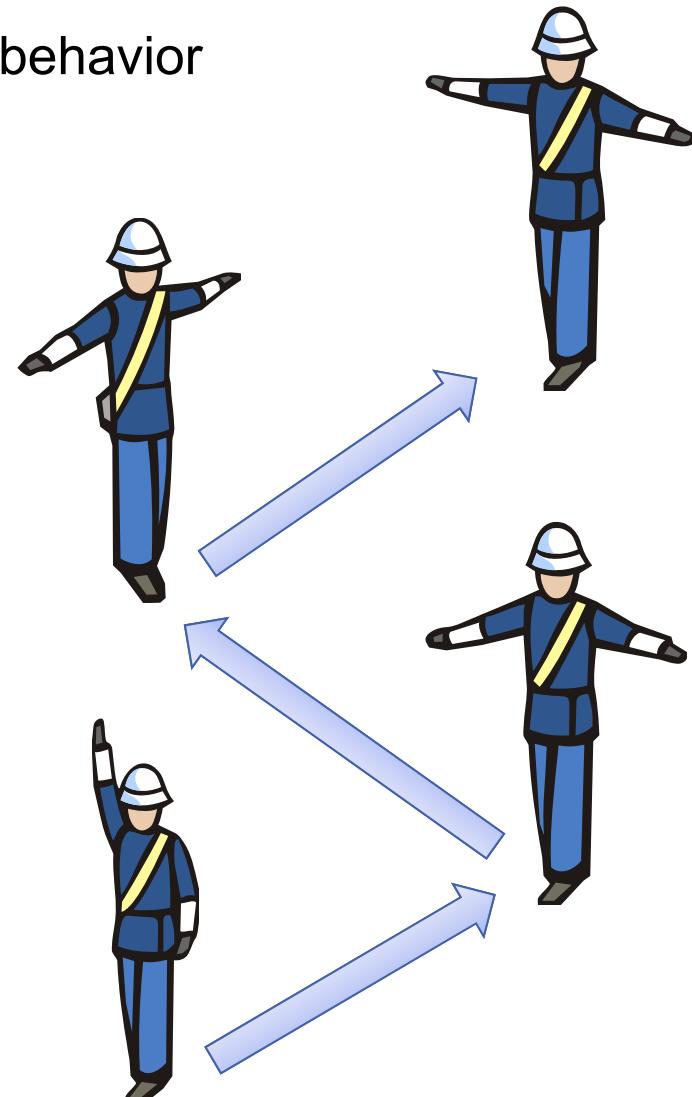

- routing computations is done in nodes
  - cooperation of nodes by means of message exchanges possible
- 
- + Easy adaptation to changing routing requirements during runtime possible
  - + Constant protocol overhead → better scalability
  - Intermediate routers get more complex

# Routing Algorithms

# Routing Algorithms

- Routing Unit implements a (pre-)defined behavior
  - connects correct IN/OUT
  - implements the communication paths
- Routing has to be defined somehow
  - Routing algorithms
- Routing Optimization Goals
  - minimal latencies
  - short routing path
  - balanced network load
- Examples of Routing Algorithms
  - X-Y Routing
  - Flooding
  - Dijkstra-Algorithm

# Routing Requirements

Usually multiple messages  $m_i$  are exchanged by multiple node pairs  $A_j$  and  $B_j$

## Routing goals

- Even Load Distribution over the network
- Minimization of *communication path or time (latency)*
- Prevention of *Deadlocks*
- Minimization of *Contention* (delay of messages due to competing requirements)
- Minimization of *Congestions* (deletion of messages, for example caused by buffer overflows)

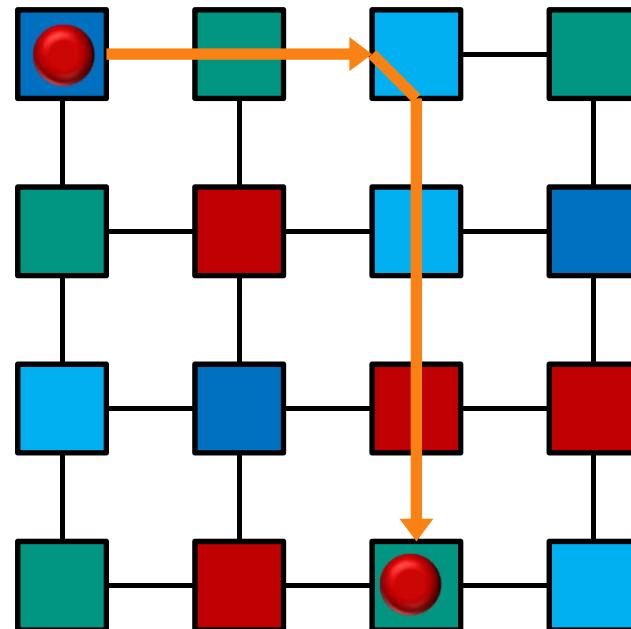

# Classification of Routing Algorithms

1. Depending on choice of path
  - Deterministic Routing
    - Unique communication path for a pair of nodes
  - Adaptive Routing
    - Multiple paths between two nodes are possible
2. Depending on length of path
  - Minimal Routing
    - always the shortest path is chosen
  - Non-minimal Routing
    - not always shortest path is chosen, for example because of congestion issues or load balancing, or ....
- Classifications are not correlated :

	Deterministic	Adaptive
Minimal	Algorithm A	Algorithm B
Non-Minimal	Algorithm C	Algorithm D

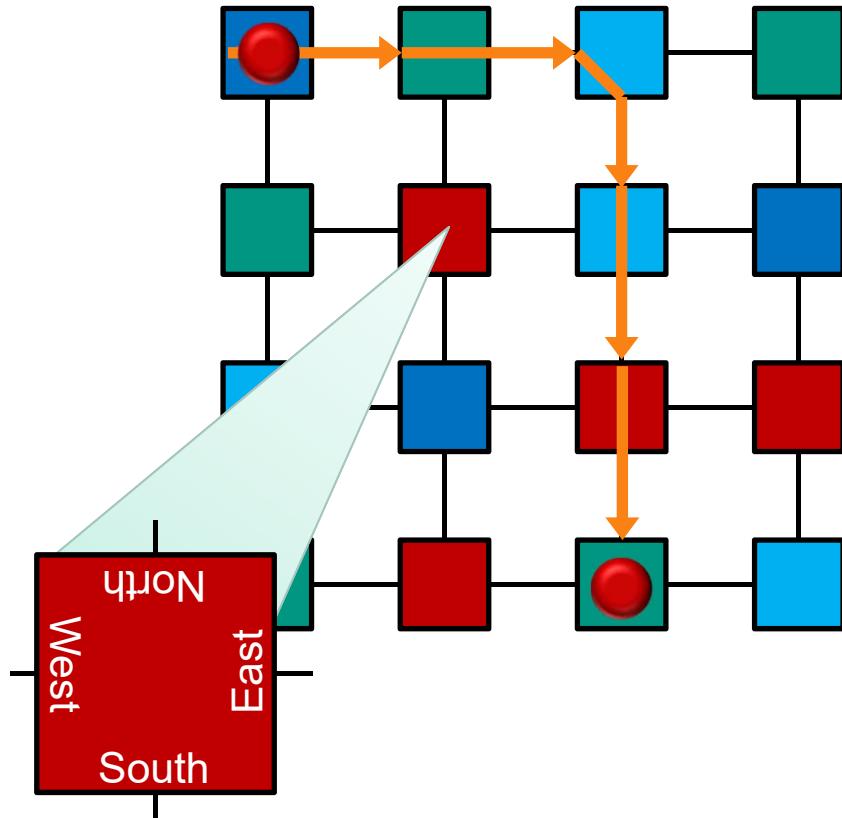

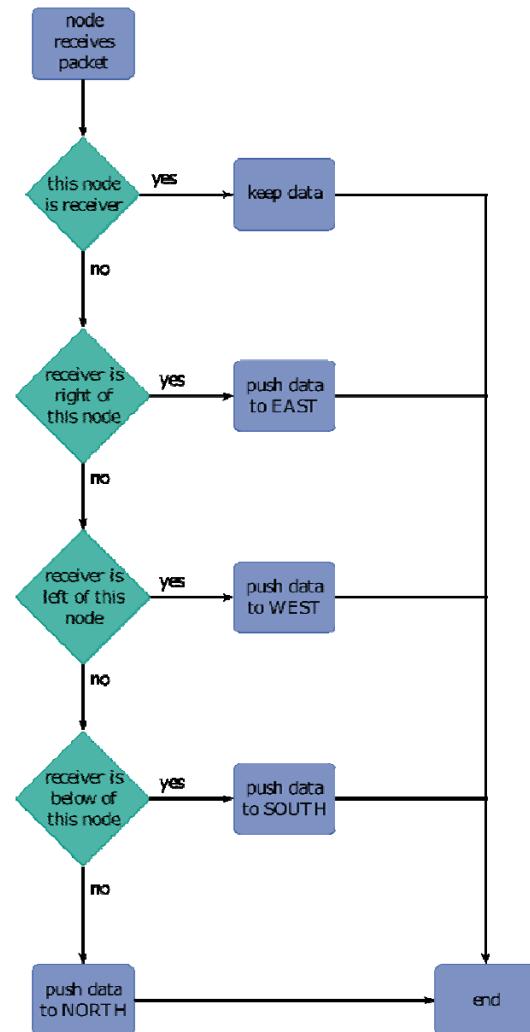

# X-Y Routing

- Only applicable for mesh based networks
- Routing always towards destination
- First in X direction, then in Y direction

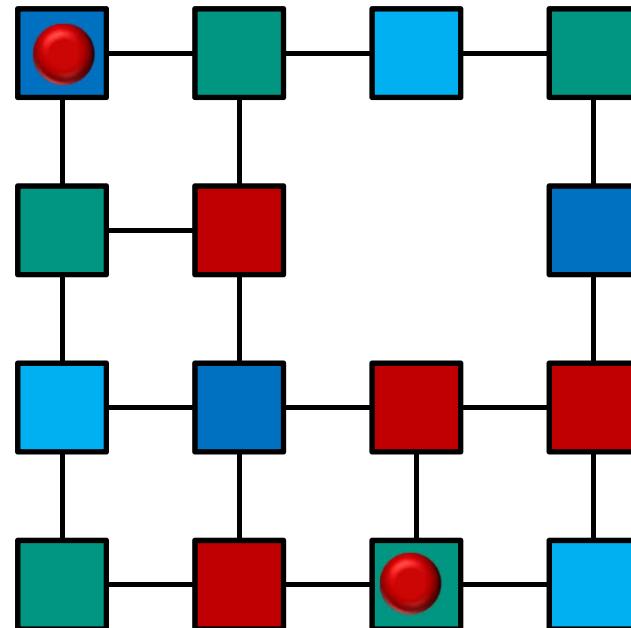

- Nodes have to know their position within the network
- Address has to be map able to the location within the network (coordinates)
- + Simple and small algorithm
- + Deadlock free
- Only works for meshes (rectangular)

# XY-Routing Implementation

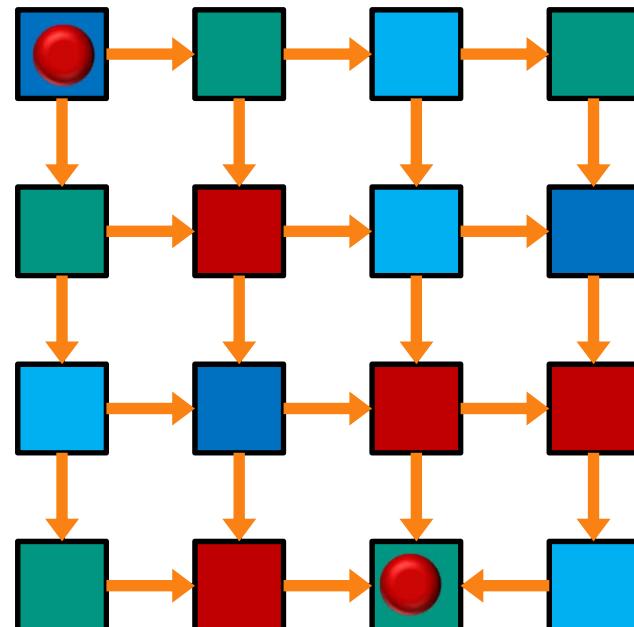

# X-Y Routing: Limitations

- How can the destination be reached in case of a missing or faulty node?

# Flooding

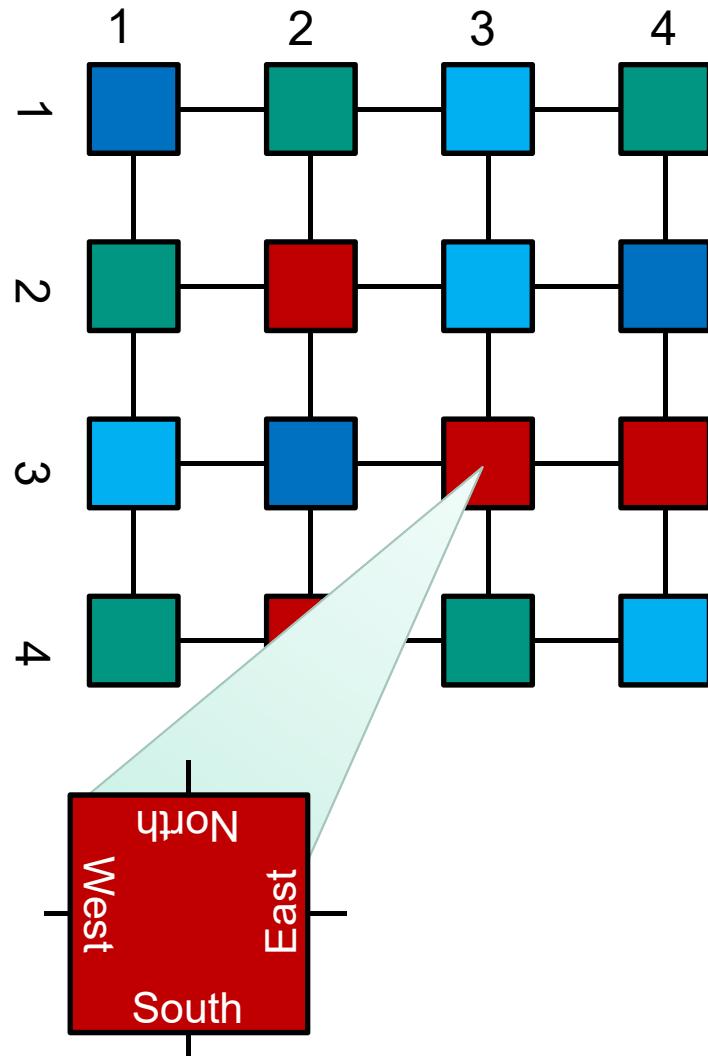

- Packets are forwarded to all ports except the receiving port
- Packet will eventually arrive at destination

- Time-to-live (TTL)
  - small number within a packet that is decreased by every router
  - if TTL = 0 packet is not forwarded
- Each packet is forwarded only once by a router
  - add Router ID to the packet when forwarding

- + No need for routing table
- + very robust
- May swamp network

# Odd-Even Turn Routing

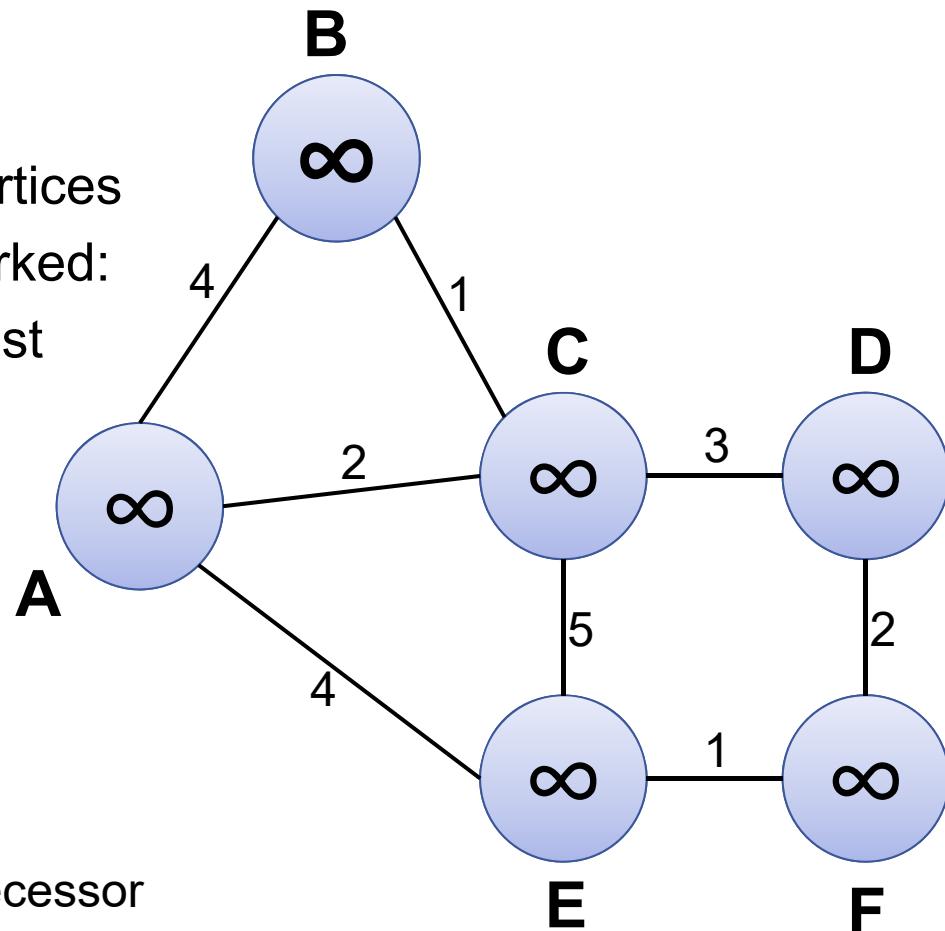

- Specialized XY Routing
- Columns and Rows are numbered
- Two rules apply:
  1. No East-North Turns in even columns  
No East-South Turns in even columns
  2. No South-West Turns in odd columns  
No North-West Turns in odd columns
- Adaptive routing:
  - Deadlock free
  - Load Balancing is possible
  - Error Tolerant
- Routing algorithm has to take care of reachability

# Dijkstra-Algorithm

- Finds the shortest path from a starting node to all other nodes in a known topology

- A. Set distance to infinity for all vertices
- B. Repeat until all vertices are marked:
  1. Mark the vertex with smallest distance
  2. For all neighbors add current distance and edge weight
  3. If sum is smaller than current distance  
→ update distance  
→ set marked vertex as predecessor

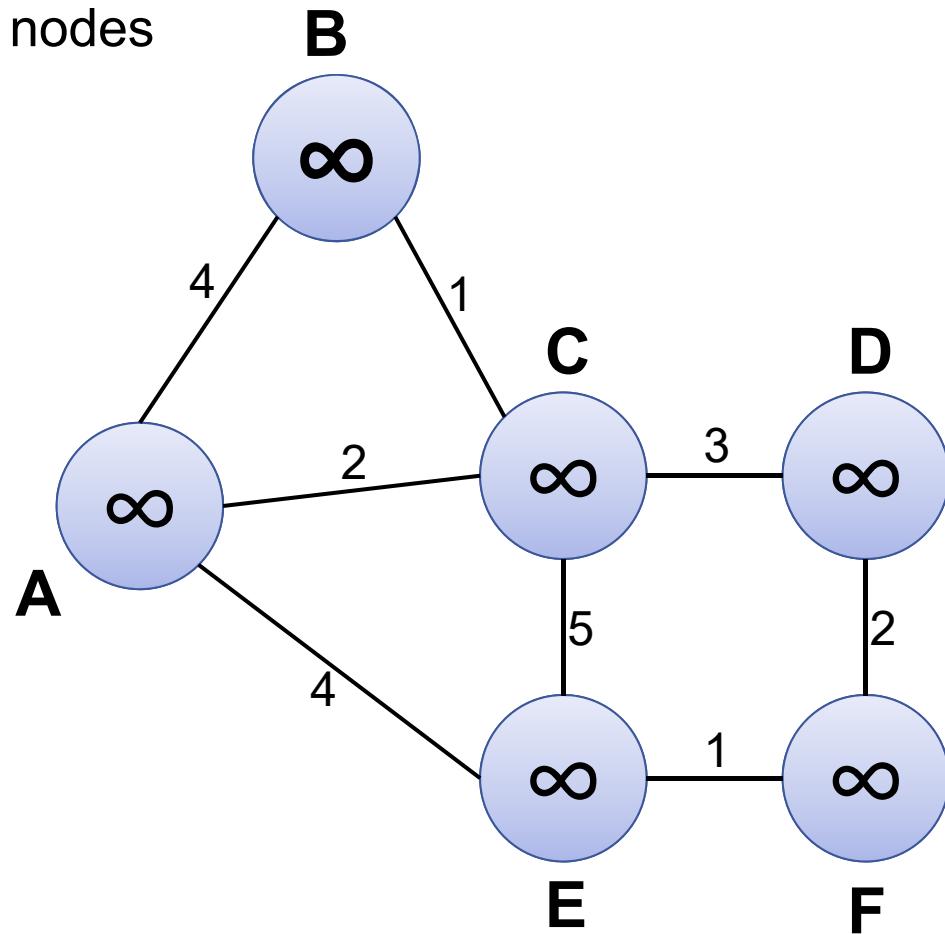

# Dijkstra-Algorithm - Example

## Step A

Vertex	Dist.	Pred.
A	$\infty$	A
B	$\infty$	-
C	$\infty$	-
D	$\infty$	-
E	$\infty$	-
F	$\infty$	-

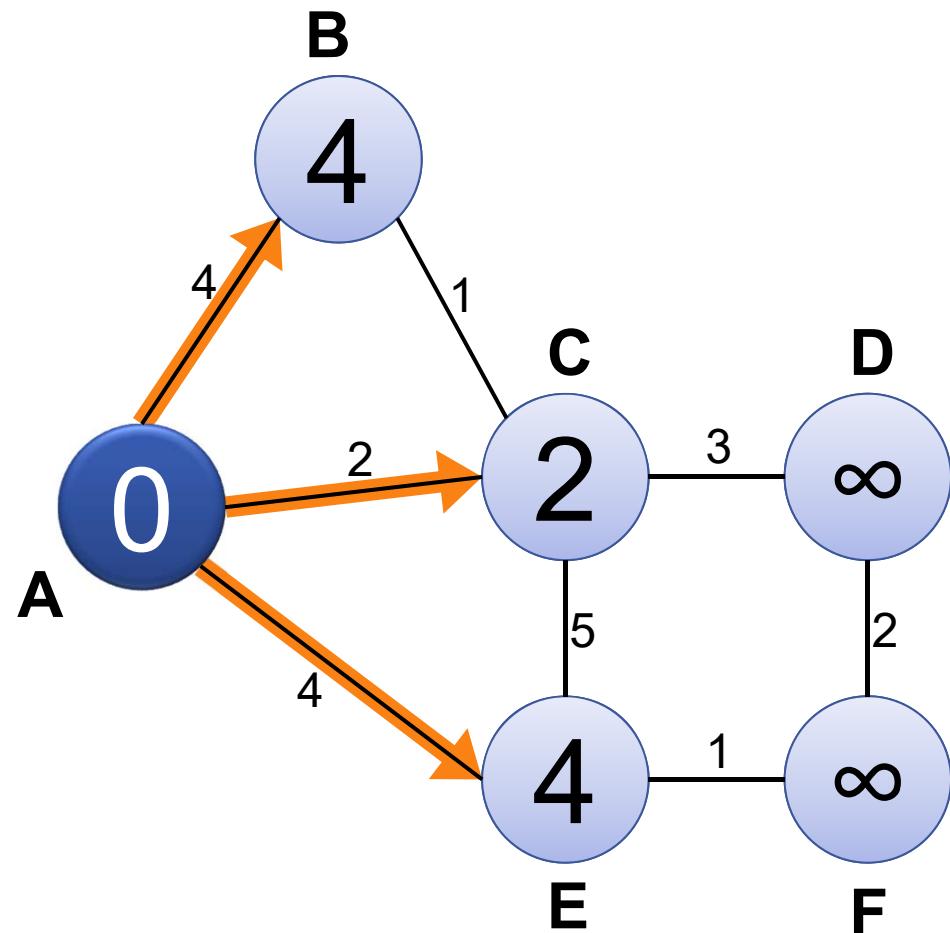

- Find the shortest path from node A to all other nodes

# Dijkstra-Algorithm - Example

**Step B**

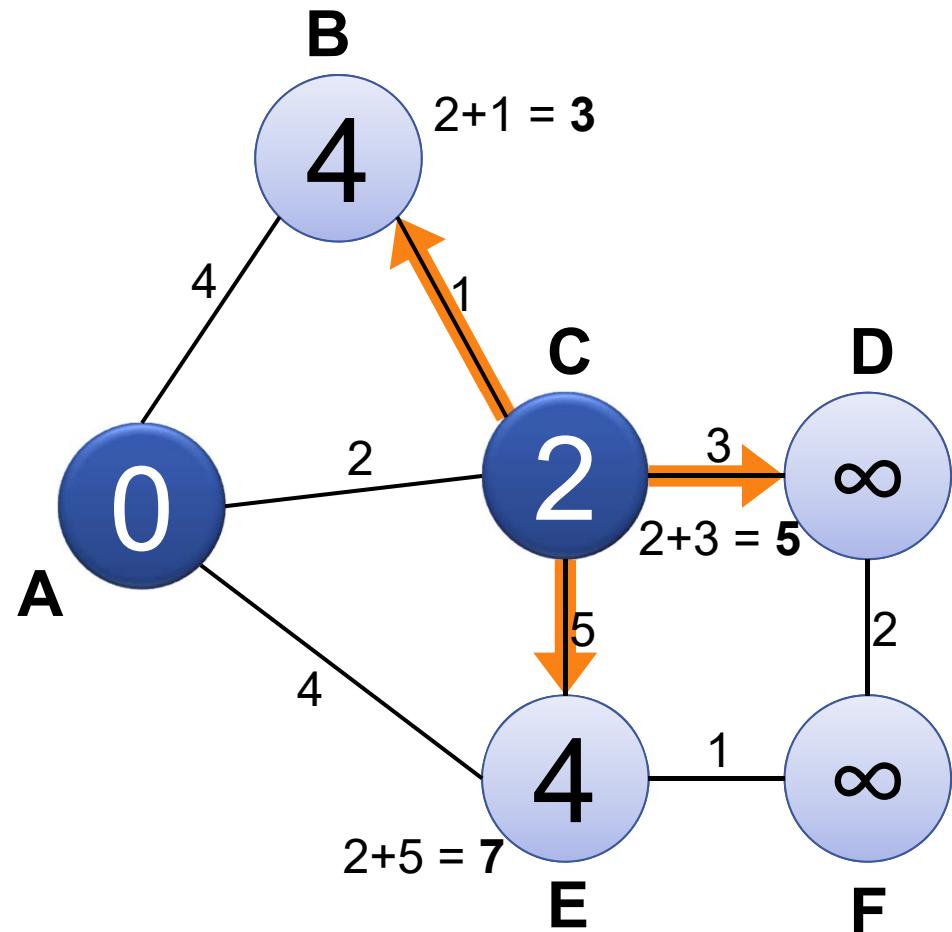

Vertex	Dist.	Pred.
A	0	A
B	4	A
C	2	A
D	$\infty$	-
E	4	A
F	$\infty$	-

# Dijkstra-Algorithm - Example

## Step B

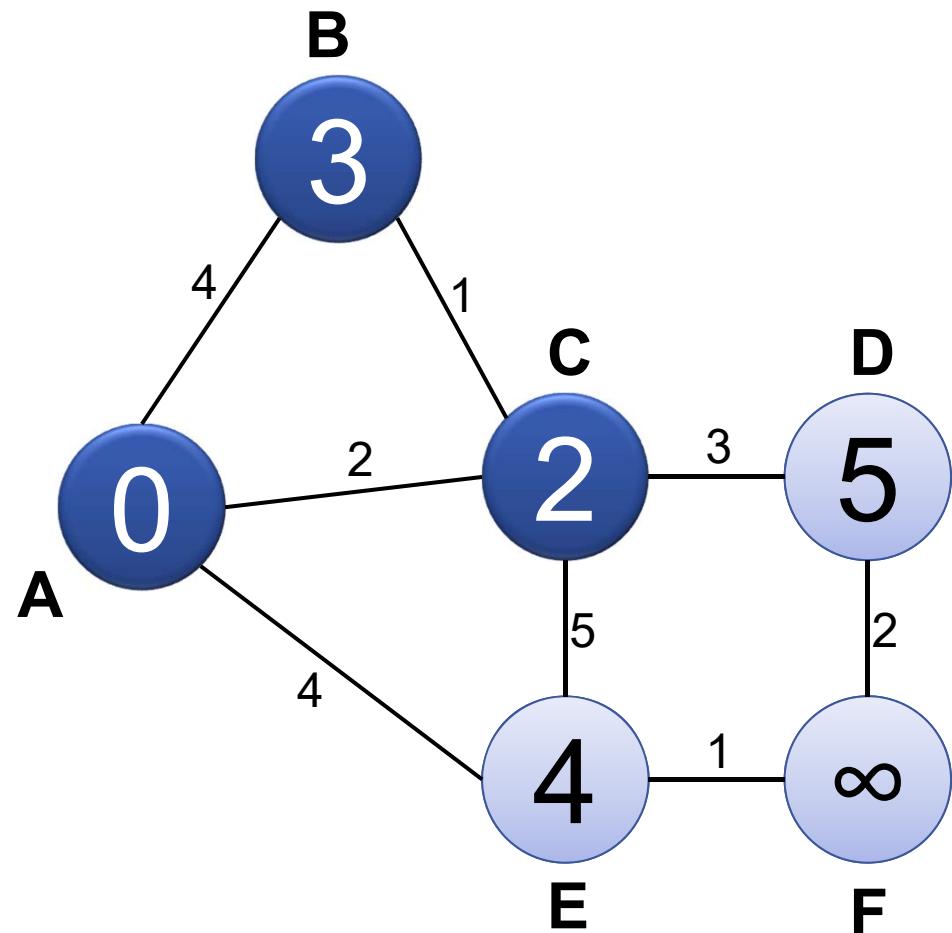

Vertex	Dist.	Pred.
A	0	A
B	3	C
C	2	A
D	5	C
E	4	A
F	$\infty$	-

# Dijkstra-Algorithm - Example

**Step B**

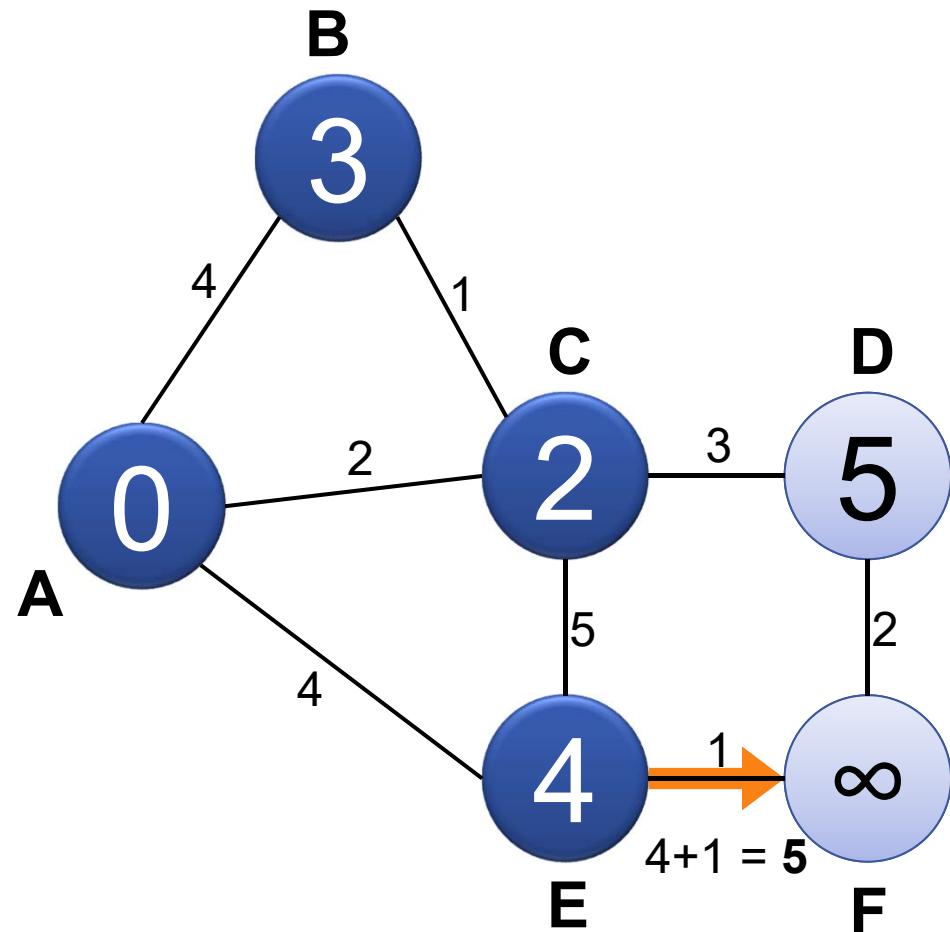

Vertex	Dist.	Pred.
A	0	A
B	3	C
C	2	A
D	5	C
E	4	A
F	$\infty$	-

# Dijkstra-Algorithm - Example

**Step B**

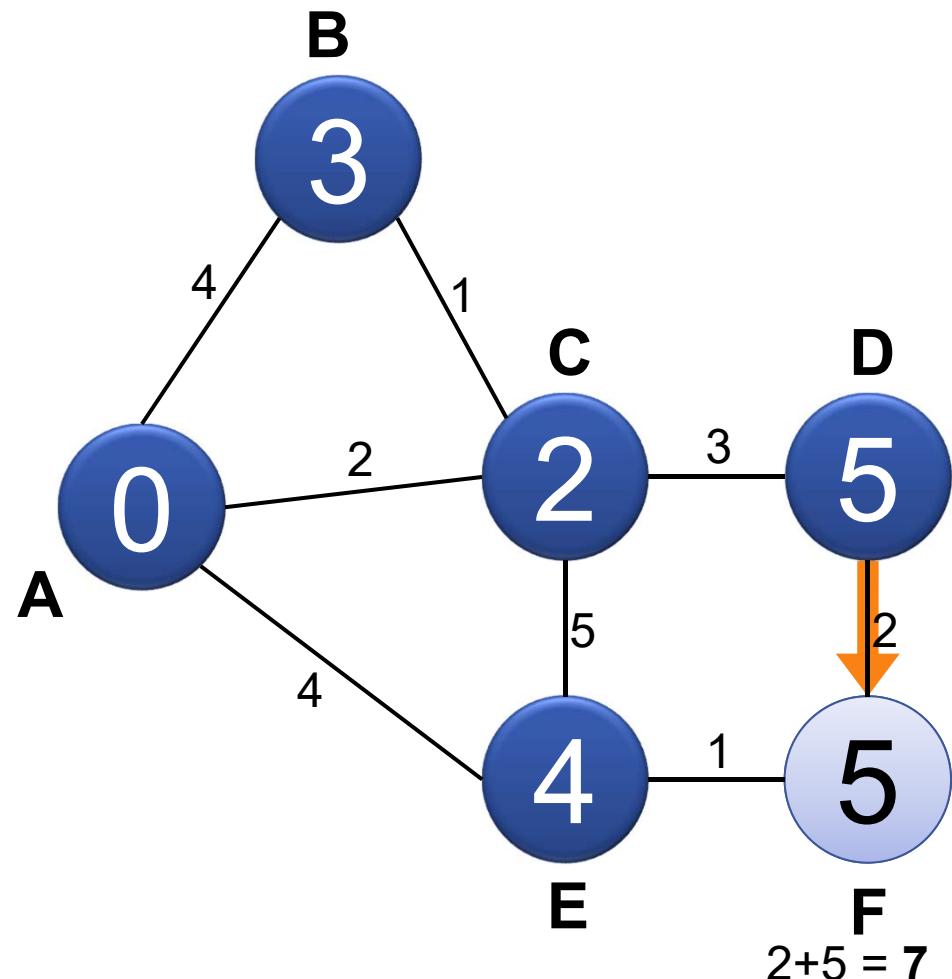

Vertex	Dist.	Pred.
A	0	A
B	3	C
C	2	A
D	5	C
E	4	A
F	5	E

# Dijkstra-Algorithm - Example

**Step B**

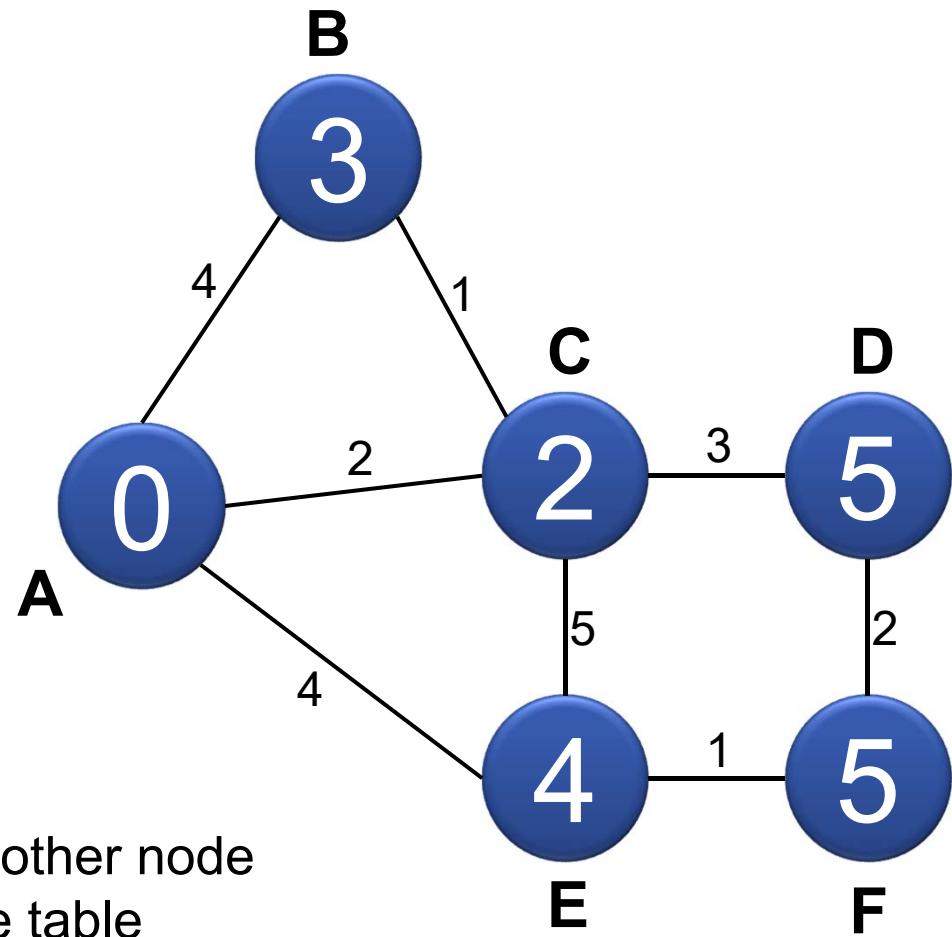

Vertex	Dist.	Pred.
A	0	A
B	3	C
C	2	A
D	5	C
E	4	A
F	5	E

# Dijkstra-Algorithm - Example

## Step B

Vertex	Dist.	Pred.
A	0	A
B	3	C
C	2	A
D	5	C
E	4	A
F	5	E

- The shortest path from A to any other node can be constructed now from the table
- For complete routing table, algorithm is repeated for all nodes

# Dijkstra – Why use it?

- Application for non-mesh-based networks
  - Distance may not be the only criteria
- Weights on Edges
  - traffic loads
  - bandwidth
  - latencies
  - ...
- Dijkstra can compute routes that are optimal regarding given constraints (weights) other than pure Manhattan distance

# Evaluation criteria for routing algorithms

- Number of hops
  - How many links are used to reach the destination?
- Latency
  - Different links can have different bandwidth
  - Can be correlated with number of hops if same time per hop
- Guarantees on bandwidth, throughput, real-time capability, etc.
  - Latency has to be known
  - Waiting time inside router has to be limited
- Robustness, failure tolerance
  - System should be still operational if one or more links are broken
  - Flow control to make sure that packets reach destination

# Outlook

- Networks
  - Node structure
- OSI Model
- Network coupling
